Motivation (1/2)

- **An Illustrative Example**: Suppose that you spin the wheel k times, and that k_i is the number of times that the outcome (money) is m_i (there are n distinct outcomes, $m_1, m_2, \ldots, m_n$)
- What is the amount of money that you "expect" to get "per spin"?
  - The total amount received is

$$m_1 k_1 + m_2 k_2 + \cdots + m_n k_n$$

  - The amount received per spin is

$$M = \frac{m_1 k_1 + m_2 k_2 + \cdots + m_n k_n}{k}$$

Motivation (2/2)

- If the number of spins k is very large, and if we are willing to interpret probabilities as relative frequencies, it is reasonable to anticipate that m_i comes up a fraction of times that is roughly equal to p_i

$$p_i \approx \frac{k_i}{k}$$

- Therefore, the amount received per spin can be also represented as

$$M = \frac{m_1 k_1 + m_2 k_2 + \cdots + m_n k_n}{k}$$

$$= m_1 p_1 + m_2 p_2 + \cdots m_n p_n$$

Expectation

- The **expected value** (also called the **expectation** or the **mean**) of a random variable X, with PMF p_X, is defined by

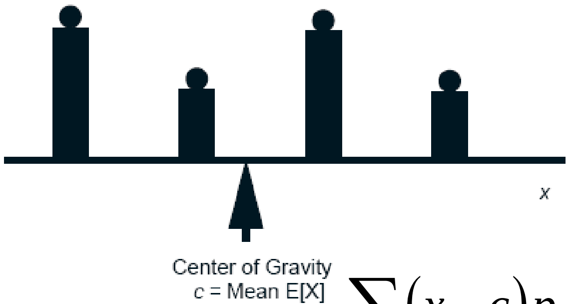
$$\mathbf{E}[X] = \sum_x x p_X(x)$$

  – Can be interpreted as the **center of gravity** of the PMF (Or a weighted average, in proportion to probabilities, of the possible values of X)

- The expectation is well-defined if

$$\sum_x |x| p_X(x) < \infty$$

  – That is, $\sum_x x p_X(x)$ converges to a finite value



$$\sum_x (x-c) p_X(x) = 0$$

$$\Rightarrow c = \sum_x x p_X(x)$$

An Example

- **Example 2.2:** Consider two independent coin tosses, each with a 3/4 probability of a head, and let X be the number of head obtained. This is a binomial random variable with parameters n = 2 and p = 3/4. Its PMF is

$$p_X(x) = \begin{cases} (1/4)^2, & \text{if } k = 0, \\ 2 \cdot (1/4) \cdot (3/4), & \text{if } k = 1, \\ (3/4)^2, & \text{if } k = 2, \end{cases}$$

$$\mathbf{E}(X) = \sum_x x p_X(x) = 0 \cdot \left(\frac{1}{4}\right)^2 + 1 \cdot \left(2 \cdot \frac{1}{4} \cdot \frac{3}{4}\right) + 2 \cdot \left(\frac{3}{4}\right)^2 = \frac{24}{16} = \frac{3}{2}$$

Moments

- The ***n*-th moment** of a random variable X is the expected value of a random variable X^n (or the random variable Y, $Y = g(X) = X^n$)

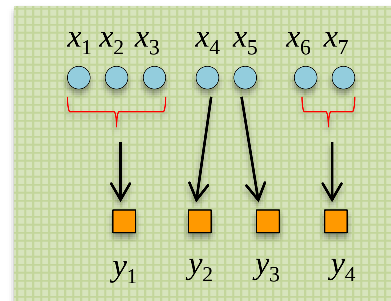
$$\mathbf{E}\left[X^n\right] = \sum_x x^n p_X(x)$$

  - The 1st moment of a random variable X is just its mean (or expectation)

X^n is termed as X raised to the power of n (or the nth power) or the nth power of X

Expectations for Functions of Random Variables

- Let X be a random variable with PMF p_X, and let $g(X)$ be a function of X. Then, the expected value of the random variable $g(X)$ is given by



$$\mathbf{E}\big[g(X)\big] = \sum_x g(x)\, p_X(x)$$

- To verify the above rule
  - Let $Y = g(X)$, and therefore $p_Y(y) = \sum_{\{x \mid g(x)=y\}} p_X(x)$

$$\mathbf{E}\big[g(X)\big] = \mathbf{E}[Y] = \sum_y y\, p_Y(y)$$

$$= \sum_y y \sum_{\{x \mid g(x)=y\}} p_X(x) = \boxed{\sum_y \sum_{\{x \mid g(x)=y\}}} g(x)\, p_X(x)$$

$$= \boxed{\sum_x} g(x)\, p_X(x)$$

?

Variance

- The **variance** of a random variable X is the expected value of a random variable $(X - \mathbf{E}(X))^2$

$$\mathrm{var}(X) = \mathbf{E}\left[(X - \mathbf{E}[X])^2\right]$$
$$= \sum_x (x - \mathbf{E}[X])^2 p_X(x)$$

  - The variance is always nonnegative (why?)
  - The variance provides a measure of dispersion of X around its mean
  - The standard derivation is another measure of dispersion, which is defined as (a square root of variance)

$$\sigma_X = \sqrt{\mathrm{var}(X)}$$

    - Easier to interpret, because it has the same units as X

An Example

- **Example 2.3:** For the a random variable X with PMF

$$p_X(x) = \begin{cases} 1/9, & \text{if x is an integer in the range [-4, 4],} \\ 0, & \text{otherwise} \end{cases}$$

Discrete Uniform Random Variable

$$\mathbf{E}(X) = \sum_x x p_X(x) = \frac{1}{9} \sum_{x=-4}^{4} x = 0$$

$$\mathrm{var}(X) = \mathbf{E}\left[(X - \mathbf{E}[X])^2\right] = \sum_x (x - \mathbf{E}[X])^2 p_X(x) = \frac{1}{9} \sum_{x=-4}^{4} x^2 = \frac{60}{9}$$

Or, let $Z = (X - \mathbf{E}[X])^2 = X^2$

$$\Rightarrow p_Z(z) = \begin{cases} 2/9, & \text{if } z = 1,4,9,16 \\ 1/9, & \text{if } z = 0 \\ 0, & \text{otherwise} \end{cases}$$

$$\mathrm{var}(X) = \mathbf{E}[Z] = \sum_z z p_Z(z) == \frac{60}{9}$$

Properties of Mean and Variance (1/2)

- Let X be a random variable and let

$$Y = aX + b$$ a linear function of X

where a and b are given scalars

Then,

$$\mathbf{E}[Y] = a\mathbf{E}[X] + b$$

$$\mathrm{var}(Y) = a^2 \,\mathrm{var}(X)$$

- If $g(X)$ is a linear function of X, then

$$\mathbf{E}[g(X)] = g(\mathbf{E}[X])$$ How to verify it ?

Properties of Mean and Variance (2/2)

$$\mathbf{E}[Y] = \sum_x (ax+b) p_X(x) = \left[a \sum_x x p_X(x) \right] + \left[b \underbrace{\sum_x p_X(x)}_{1} \right] = a\mathbf{E}[X] + b$$

$$\begin{aligned}
\operatorname{var}(Y) &= \sum_x (ax + b - \mathbf{E}[aX + b])^2 p_X(x) \\
&= \sum_x (ax + b - a\mathbf{E}[X] - b)^2 p_X(x) \\
&= a^2 \underbrace{\sum_x (x - \mathbf{E}[X])^2 p_X(x)}_{\operatorname{var}(X)} \\
&= a^2 \operatorname{var}(X)
\end{aligned}$$

Variance in Terms of Moments Expression

- We can also express variance of a random variable X as

$$\operatorname{var}(X) = \mathbf{E}\left[X^2\right] - \left(\mathbf{E}[X]\right)^2$$

$$\begin{aligned}
\operatorname{var}(X) &= \sum_x \left(x - \mathbf{E}[X]\right)^2 p_X(x) \\
&= \sum_x \left(x^2 - 2x\mathbf{E}[X] + \left(\mathbf{E}[X]\right)^2\right) p_X(x) \\
&= \left[\sum_x x^2 p_X(x)\right] - 2\mathbf{E}[X]\left[\sum_x x p_X(x)\right] + \left(\mathbf{E}[X]\right)^2 \left[\sum_x p_X(x)\right] \\
&= \mathbf{E}\left[X^2\right] - 2\left(\mathbf{E}[X]\right)^2 + \left(\mathbf{E}[X]\right)^2 \\
&= \mathbf{E}\left[X^2\right] - \left(\mathbf{E}[X]\right)^2
\end{aligned}$$

An Example

- **Example 2.4: Average Speed Versus Average Time.** If the weather is good (with probability 0.6), Alice walks the 2 miles to class at a speed of V=5 miles per hour, and otherwise rides her motorcycle at a speed of V=30 miles per hour. What is the expected time **E**[T] to get to the class?

$$p_V(v) = \begin{cases} 0.6, & \text{if } v = 5 \\ 0.4, & \text{if } v = 30 \end{cases}$$

$$\mathbf{E}(V) = 0.6 \times 5 + 0.4 \times 30 = 15$$

$$T = g(V) = \frac{2}{V}$$

$$\mathbf{E}(T) = 0.6 \times \frac{2}{5} + 0.4 \times \frac{2}{30} = \frac{4}{15}$$

$$p_T(t) = \begin{cases} 0.6, & \text{if } t = \frac{2}{5} \\ 0.4, & \text{if } t = \frac{2}{30} \end{cases}$$

However, $\mathbf{E}(T) = \mathbf{E}[g(V)] \neq g(\mathbf{E}[V]) = \frac{2}{15}$

Mean and Variance of the **Bernoulli**

- **Example 2.5:** Consider the experiment of tossing a biased coin, which comes up a head with probability p and a tail with probability $1-p$, and the Bernoulli random variable with PMF

$$p_X(x)=\begin{cases} p, & \text{if } x=1 \\ 1-p, & \text{if } x=0 \end{cases}$$

$$\mathbf{E}[X]=\sum_x x p_X(x)=1\cdot p+0\cdot(1-p)=p$$

$$\mathbf{E}[X^2]=\sum_x x^2 p_X(x)=1^2\cdot p+0^2\cdot(1-p)=p$$

$$\operatorname{var}(X)=\mathbf{E}[X^2]-(\mathbf{E}[X])^2=p-p^2=p(1-p)$$

Mean and Variance of the **Discrete Uniform**

- Consider a **discrete uniform** random variable with a nonzero PMF in the range [a, b]

$$p_X(x) = \begin{cases} \dfrac{1}{b-a+1}, & \text{if } x = a, a+1, \ldots, b \\ 0, & \text{otherwise} \end{cases}$$

$$\mathbf{E}[X] = \sum_x x p_X(x) = \frac{1}{b-a+1}\sum_{x=a}^{b} x = \boxed{\frac{a+b}{2}}$$

Note that : $\displaystyle\sum_{i=0}^{n} i^2 = \frac{n(n+1)(2n+1)}{6}$

$$\mathbf{E}[X^2] = \frac{1}{b-a+1}\sum_{x=a}^{b} x^2 = \frac{1}{b-a+1}\left(\frac{b(b+1)(2b+1)}{6} - \frac{(a-1)(a)(2a-1)}{6}\right)$$

$$\mathrm{var}(X) = \mathbf{E}[X^2] - (\mathbf{E}[X])^2 = \frac{1}{b-a+1}\left(\frac{b(b+1)(2b+1)}{6} - \frac{(a-1)(a)(2a-1)}{6}\right) - \left(\frac{a+b}{2}\right)^2$$

$$= \frac{1}{b-a+1}\left(\frac{(b-a)(b-a+1)(b-a+2)}{12}\right) = \boxed{\frac{(b-a)(b-a+2)}{12}}$$

An Example

- **Example 2.6:** What is the mean and variance associated with a roll of a fair six-sides die? If we view the result of the roll as a random variable X , Its PMF is

$$p_X(x) = \begin{cases} 1/6, & \text{if } k = 1,2,3,4,5,6 \\ 0, & \text{otherwise} \end{cases}$$

$$\mathbf{E}(X) = \frac{6+1}{2} = 3.5$$

$$\begin{aligned} \operatorname{var}(X) &= \mathbf{E}\left[X^2\right] - \left(\mathbf{E}(X)\right)^2 \\ &= \frac{1}{6}\left(1^2 + 2^2 + 3^2 + 4^2 + 5^2 + 6^2\right) - (3.5)^2 \end{aligned}$$

Mean and Variance of the **Poisson**

- Consider a **Poisson** random variable with a PMF

$$p_X(x) = e^{-\lambda}\frac{\lambda^x}{x!}, \qquad x = 0,1,2\ldots,$$

$$\mathbf{E}[X] = \sum_x x p_X(x) = \sum_{x=0}^{\infty} x e^{-\lambda}\frac{\lambda^x}{x!} = \sum_{x=1}^{\infty} \cancel{x} e^{-\lambda}\frac{\lambda\cdot\lambda^{x-1}}{\cancel{x}(x-1)!} = \lambda \underbrace{\sum_{x'=0}^{\infty} e^{-\lambda}\frac{\lambda^{x'}}{x'!}}_{1} = \lambda$$

$$\mathbf{E}[X^2] = \sum_x x^2 p_X(x) = \sum_{x=0}^{\infty} x^2 e^{-\lambda}\frac{\lambda^x}{x!} = \sum_{x=1}^{\infty} \cancel{x}\cdot x e^{-\lambda}\frac{\lambda\cdot\lambda^{x-1}}{\cancel{x}(x-1)!} = \lambda\sum_{x=1}^{\infty} x e^{-\lambda}\frac{\lambda^{x-1}}{(x-1)!}$$

$$= \lambda\sum_{x'=0}^{\infty}(x'+1)e^{-\lambda}\frac{\lambda^{x'}}{x'!} = \lambda\left[\left(\sum_{x'=0}^{\infty} x' e^{-\lambda}\frac{\lambda^{x'}}{x'!}\right) + \underbrace{\left(\sum_{x'=0}^{\infty} e^{-\lambda}\frac{\lambda^{x'}}{x'!}\right)}_{1}\right] = \lambda(\mathbf{E}(X)+1) = \lambda^2 + \lambda$$

$$\operatorname{var}(X) = \mathbf{E}[X^2] - (\mathbf{E}[X])^2 = \lambda^2 + \lambda - \lambda^2 = \lambda$$

Mean and Variance of the **Binomial**

- Consider a **binomial** random variable with a PMF

$$p_X(x) = \binom{n}{x} p^x (1-p)^{n-x}, \qquad x = 0,1,2\ldots,n$$

$$\mathbf{E}[X] = \sum_x x p_X(x) = \sum_{x=0}^{n} x \binom{n}{x} p^x (1-p)^{n-x} = \sum_{x=1}^{n} x \binom{n}{x} p^x (1-p)^{n-x} = \sum_{x=1}^{n} x \frac{n!}{x!(n-x)!} p^x (1-p)^{n-x}$$

$$= np \sum_{x=1}^{n} \frac{(n-1)!}{(x-1)!(n-x)!} p^{x-1} (1-p)^{n-x} = np \underbrace{\sum_{x'=0}^{n-1} \frac{(n-1)!}{x'!(n-1-x')!} p^{x'} (1-p)^{n-1-x'}}_{1} = \boxed{np}$$

$$\mathbf{E}\left[X^2\right] = \mathbf{E}\left[X^2 - X\right] + \mathbf{E}[X] \text{(to be verified later on!)}$$

$$\mathbf{E}\left[X^2 - X\right] = \mathbf{E}[X(X-1)] = \sum_{x=0}^{n} x(x-1) \binom{n}{x} p^x (1-p)^{n-x} = \sum_{x=2}^{n} x(x-1) \frac{n!}{x!(n-x)!} p^x (1-p)^{n-x}$$

$$= n(n-1)p^2 \underbrace{\sum_{x=2}^{n} \frac{(n-2)!}{(x-2)!(n-x)!} p^{x-2} (1-p)^{n-x}}_{1} = n(n-1)p^2$$

$$\operatorname{var}(X) = \mathbf{E}\left[X^2\right] - (\mathbf{E}[X])^2 = \mathbf{E}\left[X^2 - X\right] + \mathbf{E}[X] - (\mathbf{E}[X])^2$$
$$= n(n-1)p^2 + np - n^2p^2 = \boxed{np(1-p)}$$

Mean and Variance of the **Geometric**

- Consider a **geometric** random variable with a PMF

$$p_X(x) = (1-p)^{x-1} p, \quad x = 1,2\ldots,$$

$$\mathbf{E}[X] = \sum_x x p_X(x) = \sum_{x=0}^{\infty} x(1-p)^{x-1} p = p\sum_{x=1}^{\infty} x q^{x-1} \text{ (let } q = 1-p < 1)$$

$$= p\frac{d\left(\sum_{x=0}^{\infty} q^x\right)}{dq} = p\frac{d\left(\frac{1}{1-q}\right)}{dq} = p\frac{1}{(1-q)^2} = \boxed{\frac{1}{p}}$$

Note that: $\sum_{k=0}^{\infty} r^k = \frac{1}{1-r}, \quad \text{for } |r| < 1$

$$\mathbf{E}[X^2] = \mathbf{E}[X^2 - X] + \mathbf{E}[X] \text{(to be verified later on!)}$$

$$\mathbf{E}[X^2 - X] = \mathbf{E}[X(X-1)] = \sum_{x=0}^{\infty} x(x-1)(1-p)^{x-1} p = pq\sum_{x=2}^{\infty} x(x-1)q^{x-2} \text{ (let } q = 1-p < 1)$$

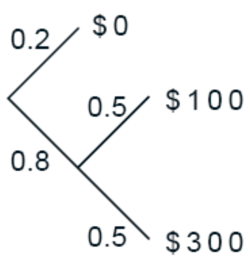
$$= pq\sum_{x=2}^{\infty} x(x-1)q^{x-2} = pq\frac{d^2\left(\frac{1}{1-q}\right)}{d^2q} = pq\frac{2}{(1-q)^3} = \frac{2(1-p)}{p^2}$$

$$\mathrm{var}(X) = \mathbf{E}[X^2] - (\mathbf{E}[X])^2 = \mathbf{E}[X^2 - X] + \mathbf{E}[X] - (\mathbf{E}[X])^2$$

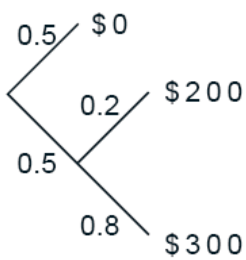
$$= \frac{2(1-p)}{p^2} + \frac{1}{p} - \frac{1}{p^2} = \boxed{\frac{(1-p)}{p^2}}$$

An Example

- **Example 2.3: The Quiz Problem.** Consider a game where a person is given two questions and must decide which question to answer first
  - Question 1 will be answered correctly with probability 0.8, and the person will then receive as prize \$100
  - While question 2 will be answered correctly with probability 0.5, and the person will then receive as prize\$200
  - If the first question attempted is answered incorrectly, the quiz terminates
  - Which question should be answered first to maximize the expected value of the total prize money received?



Question 1 Answered 1st X



Question 2 Answered 1st Y

$$p_X(x)=\begin{cases} 0.2 & , x=0 \\ 0.8\times 0.5 & , x=100 \\ 0.8\times 0.5 & , x=300 \end{cases}$$

$$\mathbf{E}(X)=0.2\times 0+0.4\times 100 +0.4\times 300=160$$

$$p_Y(y)=\begin{cases} 0.5 & , x=0 \\ 0.2\times 0.5 & , x=200 \\ 0.8\times 0.5 & , x=300 \end{cases}$$

$$\mathbf{E}(Y)=0.5\times 0+0.1\times 200 +0.4\times 300=140$$
